Nuclear power undermining climate protection

Briefing 2008
Nuclear power
undermining climate protection

Introduction

“The question is not whether climate change is happening or not but whether, in the face of this emergency, we ourselves can change fast enough.”

Kofi Annan, former Secretary-General of the United Nations, November 2006

There is a clear scientific consensus that we must halve global carbon dioxide (CO₂) emissions by 2050 or suffer changes to the global climate with catastrophic consequences. Avoiding the most severe impacts of climate change requires governments, individuals and businesses world-wide to take immediate action.

Between US $ 11 - 14 trillion are projected to be invested in new electricity generation capacity between now and 2030. The energy investment decisions taken today will determine whether or not the world achieves the necessary CO₂ emission cuts in time.

The nuclear industry, which has been in decline in the US and Europe, has seized upon the climate crisis as a revival opportunity, claiming to offer a carbon-free contribution to our future energy mix.

Nuclear power is an expensive and dangerous distraction from the real solutions to climate change. Greenhouse gas reduction targets can only be met through using the proven alternatives of renewable energy technologies and energy efficiency. Every dollar spent on nuclear power is a dollar stolen from the real solutions to climate change.
Nuclear power undermining climate protection

Too little and too late

Nuclear power could at best make only a negligible contribution to CO₂ reduction; even then many years after massive cuts are needed and only by depriving real climate solutions of funding.

Currently 439 commercial nuclear reactors¹ supply around 15% of global electricity, providing only 6.5% of overall energy consumption and only 2% of the final energy use.² The International Energy Agency’s global Energy Technologies Perspectives scenario, published in June 2008, shows that even if the nuclear capacity is quadrupled by 2050, it would only contribute by 6% to the task of halving carbon emissions from the energy sector by 2050.³ Yet, such an nuclear expansion is an impossible task: it would cost nearly 10 trillion dollars just to build new reactors, they would come online far beyond 2020, which is when the world needs to see serious cuts in greenhouse emissions already, and it would generate massive hazards linked to nuclear waste, accidents and proliferation.

In stark contrast, proven renewable energy technologies are available now, can be constructed and brought online quickly, and provide immediate cuts in greenhouse gases. For example, construction time for installing a large wind turbine has fallen to only two weeks, with an associated planning period of between one and two years.

Figure 1 Construction time of nuclear power plants worldwide

![Construction time of nuclear power plants worldwide](image)

The afore mentioned IEA ETP 2008 scenario shows that the possible contribution of renewable energies to greenhouse gas cuts is three to four times bigger than with nuclear expansion and even bigger potential lies in efficiency - and those would come without all collateral risks.

Nuclear, an expensive distraction

Investment in nuclear power stations is highly capital intensive and risky. Current forecast figures and construction schedules being provided by the nuclear industry to investors and governments are not supported by historical or even current experience. In India, for example, completion costs for the last 10 reactors have been on average three times over budget. The Olkiluoto 3 reactor under construction in Finland is already 50% over budget (see Case Study).

Alternatively, the Energy [R]evolution Scenario, commissioned by Greenpeace and the European Renewable Energy Council (EREC) (see page 6 for more information) outlines a sustainable energy pathway, phasing out nuclear power and fossil fuels, and would produce an average annual fuel cost saving up to US $ 750 billion, reaching to US $ 18.7 trillion by 2030.

There is an investment choice to be made. The investment required to quadruple global nuclear capacity would be between 6 and 10 trillion US dollars.⁴ As Amory Lovins from the US Rocky Mountain Institute calculated, in comparison to nuclear power - and already at today’s costs - wind power replaces twice as much carbon per invested dollar, and efficiency measures nearly eight times more.⁵

750 BILLION USD
CAN BE AVOIDED EVERY YEAR ON FUEL COSTS, BY USING RENEWABLE ENERGY AND ENERGY EFFICIENCY TO GENERATE ELECTRICITY.

1.5 BILLION EUROS
CURRENT COST OVERRUN FOR CONSTRUCTION OF A NEW REACTOR IN FINLAND THAT IS STILL FOURS YEARS FROM COMPLETION.
Nuclear power undermining climate protection - continued

Case Study: Olkiluoto 3 (OL3), the European Pressurised Water Reactor in Finland

The flagship of the so-called “nuclear renaissance”, the European Pressurised Water Reactor (EPR), being built in Finland, clearly illustrates the fallacy of using nuclear power to meet the climate challenge.

The International Energy Agency (IEA) warned Finland against the risk of relying on the new reactor for emission cuts, saying in 2004 that any delays would inhibit the country’s ability to meet its greenhouse gas reduction targets under the Kyoto Protocol. That risk has become a reality.

In October 2008, after 41 months of construction, the project was officially declared to be three years behind schedule and at least EUR 1,500 million (about US $2,000 million) over budget. With operation already postponed to 2012, OL3 will not be ready in time to contribute to Finland’s Kyoto target.

According to former Finnish environment minister, Satu Hassi MEP, once the decision was made to build OL3, the country lost interest in renewable energy. Similarly in 2008, Finnish Prime Minister Matti Vanhanen said: “I don’t see that (more) nuclear plants can be a global answer”, adding that reducing energy consumption, especially from cars, would do more to fight climate change.

The decision on OL3 was made at a time when new renewables, especially wind, had come of age and significant growth was projected. Projected figures have not been realised, largely because the power market is blocked by OL3, which represents 85% of the country’s planned investments in new power generation between 2006 and 2010 (See Figure 2). Similarly, we can see in Figure 3 that the commissioning of four nuclear reactors between 1977 and 1980 led to a standstill in the development of combined heat and power. The decision for OL3 is already having the same impact.

Contrary to promises that the EPR would be significantly safer, more reliable, cheaper and faster to build than earlier reactors, the project is late, over budget and has failed meet mandatory Finnish quality and safety standards. Problems have been reported with the concrete base slab, the reactor vessel, the pressuriser, and the primary cooling piping as well as with the steel liner of the reactor. All of these could have significant consequences in the case of an accident. As of August 2008, the nuclear safety authority STUK had reported 2,100 quality and safety defects with the EPR project.

The Finnish lesson is clear. Nuclear power can not deliver CO2 reductions in time, it undermines investment in clean renewable energy and energy efficiency and poses unacceptable health and safety risks.

235,000 PEOPLE
EMPLOYED IN THE GERMAN RENEWABLE ENERGY SECTOR IN 2006, AN INCREASE OF 50% ON THE PREVIOUS TWO YEARS.
A health, safety and security hazard

To propose nuclear expansion in the name of climate change is effectively adding one uncertain, potentially catastrophic health, environmental and security threat to another. Nuclear power poses an unacceptable health, safety and security risk. In fact, as climate change impacts increase, so too do the safety risks associated with nuclear power. For example, because nuclear power requires large amounts of water for cooling, more frequent droughts in a climate changed world will mean less water available to cool the reactor, leading to lower reliability and outages as nuclear plants will be forced into shut-down.

Nuclear power expansion increases the risk of an accident

Accidents happen at nuclear sites all the time. The Chernobyl accident, the worst to date, contaminated an area larger than 120,000 square kilometres and contamination was found as far away as Lapland and Scotland. The precise death toll will never be known, but may be more than one hundred thousand.\(^\text{20}\) Chernobyl’s economic impacts are estimated to be in the order of hundreds of billions US dollars. An accident in a much larger and more complex reactor, like the EPR, could have even more devastating consequences.\(^\text{21}\)

Nuclear power expansion would increase the volume and unresolved risks of spent nuclear fuel and radioactive waste far into the distant future

There is no safe solution to dealing with the dangerous radioactive waste produced by nuclear power, in spite of billions of dollars of investment and decades of research. An average nuclear reactor produces 20-30 tonnes of highly radioactive spent fuel each year, which remains radioactive for hundreds of thousands of years.

Nuclear power expansion would seriously undermine global security by significantly increasing opportunities for nuclear proliferation and terrorism

One tonne of spent nuclear fuel typically contains about 10 kilograms of plutonium – enough for a crude nuclear bomb. Experiments by the US government have proven that several nuclear weapons can be built in a matter of weeks using ordinary spent fuel from light water reactors. One study showed that a country with a minimal industrial base could quickly and secretly build a small reprocessing facility, called a ‘quick and dirty’ plant, capable of extracting about a bomb’s worth of plutonium per day from spent reactor fuel. The facility would be no longer than 40 metres and could start operation six months from start of construction.\(^\text{22}\)

The list of non-nuclear countries that have recently announced plans to gain access to nuclear technology and build nuclear reactors is long and disturbing.\(^\text{23}\) Despite extensive efforts, treaties and political mechanisms designed to safeguard nuclear materials and technology, it remains an impossible task. Mohamed El Baradei, head of the International Atomic Energy Agency, responsible for the international safeguards and security regime said in 2005:

“Export controls have failed, allowing a black market for nuclear material to develop, a market that is also available to terrorist groups.”\(^\text{24}\)

Civilian reactors and nuclear waste transports add another frightening dimension to the nuclear threat as they are attractive targets for terrorist groups.

---

**Box 1 Nuclear power and the developing world\(^\text{16}\)**

Developing countries were clear in their rejection of nuclear power as part of the Clean Development Mechanism (CDM - a mechanism under the Kyoto protocol that allows industrialised countries to invest in CO\(_2\) emission reduction projects in developing countries as a contribution towards their own domestic CO\(_2\) emission reduction targets).\(^\text{17}\)

**Nuclear power plants are too large and electricity grids incompatible** – Developing countries do not have the high-voltage grids required for large-capacity power stations. Such transmission networks are expensive and of little use in sparsely populated countries. In densely populated countries with emerging economies, long construction lead times mean nuclear power could not keep pace with increasing demand. A diverse and decentralised mix of renewable energy is a much more effective and cleaner means to meet different energy needs quickly.

**Nuclear power increases national debt** – Nuclear power stations built in developing countries add significant amounts to national debt. In the Philippines, the Bataan plant, which has never been used, was for the last twenty years the country’s largest item of overseas debt. The final payment was made this year, almost 32 years after work began.\(^\text{16}\) Twenty years since construction began, the Atucha II reactor in Argentina is still not finished despite a one billion US dollar price tag.\(^\text{19}\)

One third of the planet’s population, some two billion people, have no access to basic energy services. For these people, nuclear power is too big, too expensive and simply incompatible with their electricity grids.
Nuclear power undermining climate protection - continued

Renewable energy and energy efficiency - the only options

Greenpeace and the European Renewable Energy Council (EREC) commissioned the DLR Institute (German Aerospace Centre) to develop a global sustainable energy pathway up to 2050. This “Energy [R]evolution” scenario is a realistic blueprint for a sustainable and equitable energy future. It would maintain economic growth and achieve fairer distribution and access to energy. Most importantly, it is based on credible and proven renewable energy technologies and energy efficiency. It includes both a nuclear and a fossil fuel phase-out.

The Energy [R]evolution scenario shows that by sustaining the current double-digit growth rate of the renewable energy industry, increasing the use of combined heat and power and introducing high efficiency standards for cars, buildings and all energy consuming appliances, it is possible to generate sufficient electricity for a globally growing economy, without throwing the climate into chaos.

Figure 4 Development of global electricity supply structure under both the reference scenario and Energy [R]evolution Scenario (‘EFFICIENCY’ = REDUCTION COMPARED TO THE REFERENCE SCENARIO)
Greenpeace Recommendations

The world must get on a course to stay as far below a two degree Celsius temperature rise as possible. That course can only be reached by employing sustainable renewable energy and energy efficiency. Nuclear power is not part of the climate solution but an expensive and dangerous distraction.

• Global greenhouse gas emissions must peak and decline by 2015 and be halved by 2050.
• Binding commitments are needed for industrialised countries to cut emissions by 30% in 2020 and 80% in 2050, with domestic measures, and to direct massive funds for decarbonisation in developing countries.

An end to the nuclear age:

• Phase out existing reactors.
• No new construction of commercial nuclear reactors.
• Stop international trade in nuclear technologies and materials.
• Phase out all direct and indirect subsidies for nuclear energy.

A renewable energy future:

• Divert state funding for energy research into nuclear and fossil fuel energy technologies towards clean, renewable energy and energy efficiency.
• Set legally-binding targets for renewable energy.
• Adopt legislation to provide investors in renewable energy with stable, predictable returns.
• Guarantee priority access to the grid for renewable generators.
• Adopt strict efficiency standards for all electricity-consuming appliances.
Greenpeace

Greenpeace is an independent global campaigning organisation that acts to change attitudes and behaviour, to protect and conserve the environment and to promote peace.
